The chart looks at power density and energy density for many battery types. It includes lead-acid, nickel-based, lithium-ion, and new battery techs. This info helps you choose the best battery for your needs.

Energy storage is key in our world today. It powers everything from phones to electric cars. Batteries, which store and release energy, are at the heart of this. Knowing how batteries work is crucial.

Batteries store energy through electrochemical storage. This means chemical reactions turn electrical energy into stored energy. When charged, these reactions reverse, letting the battery release energy. This cycle makes batteries very useful.

But, higher energy density might mean lower power density and cycle life. Designers have to find the right balance for each use. This could be for longer phone battery life or better electric car range.

The energy density of batteries is key for powering devices. It shows how much energy a battery can hold in a certain size or weight. This matters a lot for things like phones, cars, and big energy storage systems.

Lithium-ion batteries are used a lot because of their high energy density. They're in electric cars, phones, and other devices that need a lot of power. As battery tech gets better, we'll see even more improvements in energy storage capacity and volumetric energy density.

Now, the battery world is full of new ideas. People are working on better energy density, safety, and performance. New tech like solid-state batteries and lithium-sulfur cells could lead to even bigger leaps in battery innovation and energy storage advancements.

Let's explore the world of energy storage. We'll look at lead-acid (SLA batteries) and nickel-based batteries. These include nickel-cadmium (NiCd) and nickel-metal hydride (NiMH). Each has its own strengths and weaknesses.

Lead-acid batteries are used in cars and for backup power. They have an energy density of 30-50 Wh/kg. This makes them reliable and affordable for starting, lighting, and ignition (SLI) in vehicles. They also provide emergency power during outages.

Nickel-based batteries, like NiCd (45-80 Wh/kg) and NiMH (60-120 Wh/kg), have higher energy densities. They are better for places where space or weight matters. NiCd batteries can handle extreme temperatures and

## Power storage battery types

charge quickly. They also last a long time, making them great for power tools and portable devices.

But, there are concerns about NiCd batteries. They contain cadmium, which can harm the environment and people. This led to the creation of NiMH batteries. They use a hydrogen-absorbing alloy instead of cadmium.
