Valletta demand response

Valletta demand response

Demand response is a critical reliability resource essential to helping the electric grid maintain the balance between electricity supply and consumer energy demand. This balance is necessary to prevent blackouts and brownouts. When energy demand increases (e.g., running air conditioning during a heat wave), there must be an adequate supply to match it. Grid operators and utilities are increasingly recognizing demand response as a cleaner, more cost-effective solution to building and maintaining peaking power plants.

Instead of capital-intensive infrastructure upgrades or firing up expensive-to-maintain peaker plants, many grid operators and utilities are realizing that the most straightforward solution for addressing peak demand is reducing it. As a result, they offer incentive programs for real-time load reduction, enabling companies to monetize their energy flexibility by participating in demand response. Demand response programs enable the grid to reduce the demand for electricity to match supply rather than the traditional method of increasing supply to meet demand.

In the dynamic world of energy management, demand response is undergoing a significant transformation due to the evolving needs of the grid. The evolution of the generation mix on the grid and the increase in intensity and frequency of extreme weather raise serious concerns about grid reliability. Demand response is no longer just about turning off lights or adjusting thermostats. It is about enabling a dynamic, responsive grid that can meet the challenges of today and tomorrow.

As the needs of both the demand and supply sides evolve, so must the strategies and technologies that balance the grid. While traditional demand response methods are effective, they are giving way to more sophistication, flexibility, and automation. As a result, various resources can be aggregated - in many cases, on-demand in real-time - to respond to the ever-changing demands of modern energy consumption and unlock multiple value streams.

Today's grid operators need a variety of flexible resources that can be called upon as necessary to support both widespread and localized issues. They need to not only plan for anticipated capacity issues but also be able to address sudden drops in supply or spikes in demand quickly. They must also keep grid frequency constant and respond to deviations in real time to avoid equipment damage. All these measures keep the lights on and prevent blackouts and brownouts, but they represent multiple value streams in which companies can participate.

In addition, many companies are now automating their demand response participation. Small and large loads can be managed with minimal human intervention to take advantage of lucrative opportunities in fast-response programs. Lead times in these programs are drastically lower - automation enables companies to respond in real time or within minutes.

Valletta demand response

The variety of demand response programs available means there"s an option to meet almost every company"s needs. Companies may have different motivators for participating in one program over another, as programs differ in payment rates, required response time, penalties (though some demand response companies, like Enel North America, shield you from penalties), and more. Some of the most common demand response program types are listed below. In many cases, companies can stack programs to maximize value.

The grid calls economic demand response programs in response to pricing spikes to help stabilize the near-term energy price level. Participating companies get paid to reduce their load in response to high prices, helping to reduce their exposure to the highest-priced hours while lowering system-wide electricity prices. As weather has become increasingly volatile, wholesale energy prices in excess of \$1,000/MWh are becoming increasingly common. ERCOT experienced over 40 such hours in August 2023 alone!

While economic demand response programs are attractive to some companies and may be the best choice based on their operational needs, it's important to note that they generally offer lower value than other demand response programs and tend to have complexity around compliance.

As part of enrollment in the capacity market, companies agree to reduce their load by a predetermined amount if/when called upon. They receive payments for their ability to reduce energy during a demand response event (capacity payment) as well as their actual energy reduction if an event is called (energy payment). In short, participants serve the grid by agreeing to be on standby and being able to perform if called upon.

Capacity demand response programs are attractive to many companies because they typically have a longer notification window. Depending on the specific program, advance notifications can range from 30 minutes to a few days ahead, giving companies time to plan their operations accordingly. They are also attractive because there are typically only a few events a year, and the duration typically lasts a few hours. As a result, they are relatively easy to plan for from an operational standpoint.

However, the grid places high value on protecting grid frequency, maintaining an acceptable voltage level, and having capacity set aside in reserves - and they pay for these services at a premium. Thus, ancillary programs pay companies for their participation significantly more than capacity programs.
